

## B. Telewriting system.

The telecrypto is constructed in such a manner that it. can be used for both 5-pulse and (after recomnection) for the 14-pulse system.

1. Telewriting system according to the international 5-pialsecode. The differont sisns are compased and transmitted by 5-pulse combinettous.

STECRE
Declassified and approved for release by NSA on 07-14-2014 pursuant to E 0.13520
sain operating systema:

> closed circuit curreut Double current mudio freguency telegraphy
inaxiaura operating speed: 7 signs per second.
2. BTK-telewriting system (Dr. E.Gretener A.-G.).

The different signs are composed and transmitted by 14-pulse combinations. The respective sigas are not printed, as f.i. vith the 5-pulse syster, in one operation, but combined from 14 different elementary signs. Each elewent correspronds to one of the 14 impulses.

Cperating system :
Audio frequency telegraphy
Maximum oferating speed : 5 signs per second
Adrantages: A much simpler construction and saller overall dimensions and weight than tnose of the 5 pulse system. Considerably sualier risks for faulty transmission, especially for radio cobmunications.

## C. Operating principles.

The telecrypto apparatus produces impulse scries of the same character as those of the telewriting apparatus employed, i.e. 5-pulse coubinations/when used in conjunction with telewriters operating on the international syster and 14-puise combinations when used with EMK-apparatus. The cryTto-impulseseries and the impulse combination of the telewriter ( clear text-impulses) will be combined, i.e. converted in the manner hereinafter described so that the cipher-iwpulse series is obtained, and this impulse-series is then transmitted.

At the receiving end these ciphered inpulse series are again converted mith an identical cipher-impulse series and the original clear text impulse series will be reconstituted. The crypto-impulses materialize every time a key on the telewriter is depressed by the start impulse of the telemriter.

Mod 1002

The composition of the crypto-impulse combinations varies inom aign to sign and the series of these variations is to all practical purposes limitless. If one f.i. mould always strike the key "a", then the ciphered impulse corbinations in the line Foula change continuously.

Fig. 3 illustrates as an example the transaission of the letter "Y", according to the 5-pulse code. 1 - 5 are the five elamentary ingulses, + when current and - no curreat.

Line 1 shows the impulse combination, produced by the telewriter, Ine 2 shows a crypto inpalse combination, in this example the combination for the letter "L". In the line 3 multipiled product of lines 1 and 2 is obtained of the elecientary impulses. The conversion is done according to the folloring rule of a wultiplication

It will be seen as a resilt of the ciphering ojeration that the letter " $0^{\prime \prime}$ is obtained in this case. If the line is, tapped with a telewriter (without telecrypto), there will be obtained the letter " 0 " instead of "Y".

Frou the lines 4-6 will be seen that the original sign combination, as produced by the sending telerriter, will be reconstituted by the multiplication of the cighered impulse combination with the corresponding crypto impulse combination.

## 5-pulse gyster.

As practicaliy all the possible differfnt impulse coubinations in this syster stand for signs (letters, numerals, punctuation signs), the ciphered impulse corbinations will give readable signs during transuiseion. The action of the telecrypto apparatus consists in this case of the exchange of signs : The letter "Y", for instance, as written on the telewriter, may be exchanged for an " $C$ " as shown in the exarile above. A person, who taps the line and has no knowledge of the cxypto impulse series edployed, vill thus obtain letters and masersls in an abgolutely Erbitrary sequence.

REF IDCAF589886

14-pulse system
With the 14 -pulse system about $16^{\prime} 000$ impulse combinations can be obtained; of these only about 50 combinations ( $=0.3 \%$ ) give readable signs. By the conversion of the clear text. combinations with those of the crypto series, there will generally be obtained unreadable impulse combinations in. the ciphered impulse series, so that an "X" may for instance be changed into $\Sigma$ etc. A telemriter, branched on to the commnication channel, and not equipped with a telecrypto apparatus, will here write unreadable signs.
D. The oiphering keys

The keying eleizents of the ciphering key serve to obtain the variable crypto-impulse series. As elements for the ciphering kejs a number of mheels (f.i. 14) are used. These pin wheels carry a number of slidable or rotatable ping, which can be displaced individuaily, by hand, and can take two different positions. In one of these positions one or several. contscts will be closed (or opened), and vice versa in the other position. Each pin is defined by a muber on the circuaference of the pin wheel (key number). qhese key numbers are also used to define the sterting positions of the pin pheels. An orerating mechanism ects on the pin wheels and noves them after each transmitted sign, in an irregular mamer. The wovement rinythm can be varied and can be changed arbitrarily by hand.

The pin wheel contacts are connected in accordance with a special system. The connections terainate at a collector, which has five sectors for the 5-pulse systew and 14 sectors for the 14-pulse system. The individual segments are either electrically activated, of not, depending on the position of the pin wheels, When a collector brush passes all segmentio, a 5-pulse or 14-pulse combination, or the so called crypto inpulse series, is obtained.

An exceedingly complicated "program" for the composition of the cxypto impulse series is obtoined on account of the
system used for the connection of the pin wheel contacts. If f.i. the first impulse element gives "current" or not may depend on the gosition of up to 12 pin wheels, ind their position at thut moment is dependent on the combinations used for the inovement of the fin wheels up to that moment.

Additional keying elements are also used, in the form of ciphering (ferutation) collectors, of shich one is alrays supplied. This is adjustable by hand. On special demand one or two extra ciphering collectors, which obtain the sume irregular kind of movement as the pin mheels, are also supplied.

The ciphering collectors are marked on their circumferences with numerals in order to define their starting positions. There are also supplied special connector plates, which can be exchanged in a very simple way.

The pin wheels and the two ciphering collectors with automatic movements PS 1 and PS 2 (Fig. 4) are mounted on a shaf't at the front end of the apparatus, while the hand operated ciphering collector PS 3 is to be found at the right hand side of cover of the machine.

## E. Composing the ciphering key settings.

He distinguish betrieen interior and exterior settings. The interior settings are changed aore or less frequently, depending on the intensity of the crypto service, while the exterior settings are composed when starting a communication series, or evertually every time a telegram is sent.

The TKG $5 / 14$ sllows the following key settings :
a) Interior key settings.

1. The positioning of the pins on the pin wheels, which total about 500.
2. Arbitrary arrangewent of the movement program for the 14 pin wheels and the two ciphering collectors.
3. The choice of different connection plates for the ciphering collectors.
b) Exterior key settings
4. The starting positions of the 14 pin wheels at the beginning of the communication, sbout 35 different positions for each pin wheel are possible.
5. The sturting yositions of the three ciphering collectors, each collector can take 28 different positions.

Both the interior and the exterior keys can be set by hand without any tools.

To set the pin wheel pins, as well as the starting positions of the pin wheels, a rlexiglass cover is opened with the aid of the lever "Hi", when a sufficiently large sector of each pin wheel will be uncovered.

In order to compose the movenent program for the pin wheels and ciphering collectors, the protective cover " $A$ " is opened. The changes can be made by varying the position of contact plugs.

It should be noted that the different key elenents can be adafted within reasonable liaits to the needs of the customers, with regard both to construction and viring diagrams.

The construction of the tEG $5 / 14$ apparatus offers an exceptionally high degree of safety, when fully equipped. In many cases the equipment can be simplified; the wishes of the customer can be taken into account.

The teleorypto will be built in such a way that the same apparatus can be used together fith telewriters according to the 5 -pulse or the 14 -pulse system. The change-over from one systec to the other is done by changing the position of a connecting plag "J", after removing the cover plate "P" (Fig. 4), and by the exchanging of two gear wheels.

The telecrypto apparatus will be built for

2. 5-pulse double current 14-rulse ETT
3. 5-pulse ETT

14-pulse ETT
or
according to the wishes of the customer.

Wire or radio can be used as coumunication channels. In case of radio the swaller sensitivity of the 14 -pulse system against perturbations should be noted.

## F. Electrical dater.

The telecrypto apparatus cun be used with :

1. $110,125,145,220$ and 250 volts alternating current, 50 cycles
Fover consumption abt. 100 VA .
2. 12 volt direct current (Battery)

Power consumption abt. 70 Watts.
G. Hechanical construction, dimensions and weight.

The telecrypto apparatus consists, as will be seen on Fig. 4, of a frame of sheet metal UT, which contains the electrical elements such as vacuur tubes, transformer, resistances, condensers etc. and of an upper part Of, which contains the mechanical elements : motor, gears, cipharing collectors, fin wheels etc. The upper part is hinged on the base, and by tilting it up, all parts in the interior of the base will be easily accessible.

A carrying case is provided for the transportation of the apparatus.

The dimensions of the TKG $5 / 14$ will be seen onf Fig. 4. They are :

| Width | Depth | Height |
| :--- | :--- | :--- |
| 410 mm | 350 mm | 225 mm |

The weight is about 55 lbs . ( 25 kg .)

## H. Operation.

After having conuected the telecrypto to the mains, or to a battery, and to the telewriter, service comanication is first established in clear text. The larap $L_{1}$ indicates that the apparatus is connected. The switch $S$ is set in the position "clear" which disconnects the ciphering mechanism of the telecrypto. In this fosition a red lamp $L_{2}$ warns that clear text is being sent. isfter having sent the routine wessages, and after buving rede all key settings, the switch is changed over to "Crypto", after which the secret comunications can start.

When the transmission conditions are poor, f.i. atmospheric disturbances when using radio channels, it may happen that the two telecrypto apparatus fall out of step. From this moment the deciphering at the receiving end will become faulty, so that the receiving telewriter will not write clear text any longer.

The operator at the receiving end vill in this case strike the special key of his telewriter, which interrupts the transmission. Both operators then put their switches $S$ in the "clear" position. In order to avoid the tedium of making new settings of the secret keys, a counter "ム" is provided for, which automatically counts the nuwber of operations of the telecryntos. In order to put the two telecryptos into step again, the operator of that station, whase telecrjpto got behindhand, has only to press the button $D$ a number of times, until his counter shows the same number as his correspondents. When this is obtained, the switch $S$ is put back into position "Crypto", and the transmission of the secret message can be continued.
